

Outcome Monitors: Recovering Silent Tool Failures in LLM Agents

Sugam Author¹, Rabab Abdelfattah¹

¹AIMS Lab, University of Southern Mississippi

Modern artificial intelligence (AI) systems are powered by foundation models that increasingly act through external tools. When a tool call fails silently, the agent's downstream reasoning proceeds on stale or fabricated state. This paper presents Outcome Monitors, a lightweight observability layer that detects unacknowledged tool failures from the conversation trace alone. We evaluate across three agent frameworks and find that advisory detection recovers a large fraction of silent failures without modifying the underlying policy. This abstract is placeholder text demonstrating the AIMS Lab header format; replace it with the real abstract of your paper.

1 Introduction

Foundation models are general models of language, vision, speech, and/or other modalities that are designed to support a large variety of AI tasks. This body text exists only to show how the page continues after the header box, matching the layout of the Llama 3 technical report.
